ABSTRACT

The large-scale nature of product catalog and the changing demands of customer queries makes product search a challenging problem. The customer queries are ambiguous and implicit. They may be looking for an exact match of their query, or a functional equivalent (i.e., substitute), or an accessory to go with it (i.e., complement). It is important to distinguish these three categories from merely classifying an item for a customer query as relevant or not. This information can help direct the customer and improve search applications to understand the customer mission. In this paper, we formulate search relevance as a multi-class classification problem and propose a graph-based solution to classify a given query-item pair as exact, substitute, complement, or irrelevant (ESCI). The customer engagement (clicks, add-to-cart, and purchases) between query and items serve as a crucial information for this problem. However, existing approaches rely purely on the textual information (such as BERT) and do not sufficiently focus on the structural relationships. Another challenge in including the structural information is the sparsity of such data in some regions. We propose Structure-Aware multilingual LAnguage Model (SALAM), that utilizes a language model along with a graph neural network, to extract region-specific semantics as well as relational information for the classification of query-product pairs. Our model is first pre-trained on a large region-agnostic dataset and behavioral graph data and then fine-tuned on region-specific versions to address the sparsity. We show in our experiments that SALAM significantly outperforms the current matching frameworks on the ESCI classification task in several regions. We also demonstrate the effectiveness of using a two-phased training setup (i.e., pre-training and fine-tuning) in capturing region-specific information. Also, we provide various challenges and solutions for using the model in an industrial setting and outline its contribution to the e-commerce engine.

CCS CONCEPTS

• Information systems \rightarrow Retrieval models and ranking; Query representation; • Applied computing \rightarrow Online shopping.

1 INTRODUCTION

The goal of an e-commerce search engine is to show a ranked list of items that best match a shopper's query intent. Unlike standard search engines [13, 17], e-commerce engines cannot solely rely on the textual and semantic content of a query. This is because shoppers' queries are often ambiguous, broad, lack specific intent or have an implicit intent. A simple one-size-fits-all approach to ecommerce product retrieval seldom works for all types of customer queries. Practitioners often mitigate this using additional human labeled data to re-rank items or aptly message the shoppers as to why an item was surfaced. The shopper may be looking for an exact match for their query, or a functional equivalent (i.e., *substitute*), or an accessory to go with it (i.e., complement). It is important to distinguish these three categories from merely classifying an item as relevant or not for a given query. Specifically, annotated data is used to classify query and item pairs into Exact (E), Substitute (S), Complement (C), and Irrelevant (I) (ESCI) classes.

Obtaining human annotated data is time consuming and costly. The size of datasets available to train ESCI classification models is orders of magnitude smaller than those used to train relevance models [4] (which typically rely on anonymized aggregated customer shopping behavior). In addition, the labeled data available per-region to train these models is even smaller. However, there is additional information that is present in e-commerce datasets, in the form of query-item graphs capturing interactions between these pairs, and co-purchase behavior across products in the catalog. We hypothesize that one can train better ESCI classifiers by aggregating information along nodes and edges of this graph to extract queries and items that are similar to the ones in the labeled dataset.

Models that use graph information have shown to be competitive in e-commerce search applications. These models typically tend to outperform their pointwise or pairwise counterparts such as C-DSSM [21, 28] and MV-LSTM [32], and their adversarial [20] or multilingual [1] extensions. This is because the aforementioned methods only focus on the textual information in the query-product pairs, and ignore any relational information across queries and products. However, existing approaches work with very small graphs, and are not built to scale to the sizes of graphs typically seen in the real-world applications. In this paper, we propose **Structure-Aware**

multilingual LAnguage Model (SALAM), illustrated in Figure 2, that combines text and graph information in a scalable manner, overcoming the drawbacks of the aforementioned methods.

Figure 1: Sample of a query-product pair with (a) only text and (b) text and graph structure. Note that classifying the relation in (a) based only on text is difficult because both the products have a single token match with the query. However, with the aid of graph structure in (b), the classification becomes easier with more semantic token matches and additional information about the relations.

Academic research in this topic has explored certain solutions to the problem of integrating text and graph using hybrid techniques such as TextGNN [40], TextGCN [35], and Graphormer [37]. However, these approaches are not scalable to industrial applications which typically need to handle hundreds of millions of queries everyday and require low processing latency.

SALAM is first pretrained on a corpus of labeled data across multiple regions as well as the query-product graph. This allows for a model that can be initialized using *all* the labeled data available. Next, SALAM is fine-tuned on region-specific labeled datasets. We show via extensive experiments that the use of auxiliary graph structured information and the proposed two-stage training approach vastly outperforms baseline methods by 10%-65% across multiple regions. The specific architectural choices in SALAM also allow it to be deployed in web-scale systems. SALAM utilizes a mul-

Figure 2: An overview of the proposed SALAM. Given the input query-product pair with their corresponding local neighborhoods, SALAM combines the power of textual and graph representations for ESCI classification.

tilingual language model (MLM) [5] in congruence with a Graph Convolution Network (GCN) [15], to capture the textual and graph features of query-product pairs, respectively. These features are combined in the latent space with an attention layer [30] to capture the inter-dependency between the textual and graph-based

features, which are further utilized for the final ESCI classification. To summarize, the major contributions of this paper are as follows:

- (1) We present Structure-Aware multilingual LAnguage Model (SALAM) that combines a MLM and GCNs within an attentionbased framework to aggregate features from both the text and graph attributes of query-product pairs, respectively. We show that the proposed unique aggregation mechanism is able to outperform the current state-of-the-art models on the task of ESCI classification with similar computational resources and model latency limits.
- (2) We demonstrate the benefits of utilizing the graph features and attention aggregation through an ablation study.
- (3) We illustrate the performance gains in multi-region/multilingual classification produced by using a two-phase (pre-training and fine-tuning) approach over one that trains a single model.
- (4) We detail the challenges that affect the practical viability of SALAM in industrial settings, and provide solutions for the same. We also outline the primary benefits of our approach to an e-commerce search engine.

The rest of the paper is organized as follows; Section 2 presents the related literature in this topic. Section 3 defines our problem statement and the model architecture. Section 4 describes our experimental results in a comparative evaluation and Section 5 presents our deployment strategy along with the contributions of the model to the e-commerce engine. Section 6 concludes the paper.

2 RELATED WORK

In this section, we describe the earlier works relevant to our current problem. We present three broad areas of representation learning: graph, text, and hybrid (graph+text) methods.

Graph Representation Learning. Earlier research into graph embeddings relied on two broad methods: matrix factorization and random walks. Matrix factorization methods [22, 26] attempt to factorize the adjacency matrix A to a low-dimensional representational matrix L by minimizing $||L^TL - A||$. Random walk techniques [10, 19, 25, 29, 33] utilize a traversal along the edge connections of a node to retrieve its neighborhood and learn the representation. These approaches form a vector space model based on the node's neighborhood and have shown the importance of learning graph representations. However, these methods depend on the methodology of the random walk traversal technique and do not handle the entirety of a node's neighborhood. Hence, we utilize the power of deep networks to aggregate features from the nodes' neighborhood. Some of the popular deep architectures include Graph Neural Network (GNN) [27], GraphSage [11], Graph Convolution Network (GCN) [15], and Graph Attention Network (GAT) [31]. In our proposed SALAM model, we utilize the scalable GCN architecture for learning features from the graph structure of query-product pairs.

Text Representation Learning. Early research in text embeddings relied on capturing the context of individual words (or tokens). These approaches [18, 24] show the effectiveness of distributional representations in extracting semantic features. However, most of the problems that involve text need sentence embeddings and not word-level representations. Towards this, text representations evolved to utilize sequential word information using recurrent networks [32], convolution networks [28], and attention networks [2].

Recently, newer techniques are based on learning a pre-trained language model [6, 8] that can be fine-tuned on specific tasks. Such approaches have shown improved performance over the other representational techniques. Thus, in our model, we utilize this two-step approach, i.e., pre-training and fine-tuning steps, to capture region-agnostic and region-specific information, respectively.

Hybrid (Graph + Text) Representation Learning. Recently, we see an increasing research effort focused on extracting hybrid graph and text information from structured datasets. TextGNN [40] and TextGCN [35] utilize text embeddings to initialize node features in a graph network framework. Graphormers [38] utilize manual graph features (such as spatial encoding and centrality measures) within a text-based transformer architecture to capture hybrid features. These methods, while effective, are not scalable to a practical application that receives millions of queries per day and hence, we developed SALAM as an effective architecture with low latency. Another line of approaches [9, 36] focus on the problem of structured reasoning for question answering. However, these approaches require specific relational knowledge graphs which are, generally, not readily available and require significant investment for construction. Our model uses the platform generated purchase information for knowledge and hence, does not need any additional investment.

3 MODEL ARCHITECTURE

In this section, we first discuss the problem statement and then explain the different components of our architecture and detail its training and inference pipeline.

3.1 Problem Statement

Let us say that the input query-product pair is (Q, P). From a global graph \mathcal{G} , we pre-compute their neighborhood based on historical purchase information as $Q_{\mathcal{G}}$ and $P_{\mathcal{G}}$, respectively. The goal of this work is to build a prediction model P_{θ} with parameters θ such that

$$\hat{y} = \underset{y' \in \{E, S, C, I\}}{\arg \max} P_{\theta}(y'|x, \theta); \quad \theta = \underset{\theta}{\arg \max} P_{\theta}(\hat{y} = y|x, \theta) \quad (1)$$

where \hat{y} is the predicted output of model P_{θ} for a corresponding input sample $x = (Q, P, Q_{\mathcal{G}}, P_{\mathcal{G}})$ and $y \in \{E, S, C, I\}$ is the ground truth label for the sample x.

3.2 Model Components

In this section, we describe the function of different components of SALAM and show their hybrid graph-text feature extraction and aggregation methods. As shown in Figure 3a, we begin the pipeline with an input query-product pair either received from a user or a collection of historical queries, x=(Q,P). Using x, we compute the corresponding graph neighborhoods $x_{\mathcal{G}}=(Q_{\mathcal{G}},P_{\mathcal{G}})$ using the Graph Construction module. The textual features of the input pair are then encoded using a language model and the neighborhood $x_{\mathcal{G}}$ is aggregated using a Neighborhood aggregation network to produce two complementary representations $t_{Q,P}$ (based on text) and $g_{Q,P}$ (based on graph). These representations are then pooled together using attention to finally produce the probabilities $P_{\mathcal{G}}(y'|x,\theta)$ using a normalizing function (i.e., softmax). We will

now provide more specific details of these components used in our model.

Graph Construction. In this module, we pre-compute a local neighborhood of connections between queries and products. Several such query-product graphs are, generally, available in the context of e-commerce engines such as purchase information, retrieval history, and click-through rates. For simplicity, in our problem, we utilize the purchase information, i.e., a query node and product node have an edge between them if the product has been purchased for a given query, else no edge exists. To construct the neighborhood, we perform a breadth-first traversal over the root node till a depth threshold of n^1 . Additionally, we also store the corresponding nodes' features as semantic encoding of its text, obtained from a pre-trained XLM model [6]. The graph $x_{\mathcal{G}} = (Q_{\mathcal{G}}, P_{\mathcal{G}})$ for query-product pair x = (Q, P) is stored in a hash map for constant time retrieval during the training and inference phase.

Language Model. To encode the text attributes (Q, P), we adopt the multilingual XLM [6] model². For a pair of text sequences, the language model provides a sequence of encoding of $e \in \mathbb{R}^F$, which is further reduced to $t \in \mathbb{R}^f$, (where $f \ll F$) through a dense linear layer, $\phi_F^f : \mathbb{R}^F \to \mathbb{R}^f$ for computational efficiency in the attention pooling and final classification layer.

$$t_{Q,P} = \left\{ \phi_F^f(XLM(Q,P)) \right\}^f \tag{2}$$

where $\{X\}^f$ implies that X is a feature vector of f dimensions.

Neighborhood Aggregation. In SALAM, we use a Graph Convolution (GCN) encoder [15] to encode the graph neighborhood of the query-product pair. The choice of the graph encoder is dependent on the trade-off between its performance and scalability on the huge e-commerce purchase information. From our experiments, described in Section 4.4, we chose GCN due to its performance advantage over other graph encoders with similar parameters. Let us say the input to a GCN for a neighborhood of N nodes with feature dimensions F is given by $h_0 \in \mathbb{R}^{N \times F}$. An L-layer GCN aggregates the node neighborhood into features as:

$$h_{l+1} = \sigma \left(D^{-\frac{1}{2}} A D^{-\frac{1}{2}} h_l W_l \right) \tag{3}$$

Thus,
$$GCN(h_0) = \{h_L\}^f$$
 (4)

where h_l and h_{l+1} are the input and output to the l^{th} GCN layer. W_l is the learnable feature map for the layer and σ is a non-linear activation function. $D \in \mathbb{R}^{N \times N}$ and $A \in \mathbb{R}^{N \times N}$ are the diagonal degree and adjacency matrices of the graph, respectively. h_L is the output of the final GCN layer and consequently the encoding of the nodes' neighborhood.

Applying this to the given input graph of query-product pair $x_{\mathcal{G}} = (Q_{\mathcal{G}} \in \mathbb{R}^{N \times F}, P_{\mathcal{G}} \in \mathbb{R}^{N \times F})$ with node features $Q, P \in \mathbb{R}^{F}$, we independently encode the neighborhood graphs of both the query and product using GCNs and then concatenate (\circ) the resultant features for the final output, $g_{Q,P}$ as given below:

$$\{g_{Q,P}\}^{2f} = \{GCN(Q_{\mathcal{G}})\}^f \circ \{GCN(P_{\mathcal{G}})\}^f$$
 (5)

¹Due to computational constraints, we empirically set n to be 2.

 $^{^2}$ XLM is chosen due to its popularity and multilingual nature, any other trainable multilingual text encoder can be used as an alternative.

Figure 3: An overview of SALAM's architecture (a) and its training (b) and inference (c) pipelines. (a) The inputs to the architecture are a query-product text pair with a pre-computed graph neighborhood which is obtained from the purchase information. The textual and graph features are encoded using a language model and GCN, respectively. Subsequently, the concatenation of the features are pooled with an attention mechanism to finally predict the probability of the classes. (b) The training pipeline uses the query database and product catalogue with a ground truth label for back-propagation and saves a model checkpoint on convergence. (c) The inference pipeline employs the checkpoint to classify search relevance on a user query and products from the catalogue to generate the final label, which is stored in the database for relevance computation in the e-commerce engine.

Attention Pooling. The graph and text features, while encoded independently, are derivatives of the same e-commerce dataset. Hence, our current encoding misses the inter-relations between the features. To capture these dependencies, we rely on an attentive pooling mechanism [30] that calculates attention weights to higher order interactions between the nodes' text and graph features to subsequently combine them into a single feature set. The final output of the attentive pooling between the graph and text features, $o_{O,P}$, is computed as:

$$\left\{ e_{Q,P} \right\}^{3f} = \left\{ t_{Q,P} \right\}^f \circ \left\{ g_{Q,P} \right\}^{2f} \tag{6}$$

$$\{q_{Q,P}\}^h = \phi_{3f}^h (e_{Q,P}); \ \{k_{Q,P}\}^h = \phi_{3f}^h (e_{Q,P}); \ \{v_{Q,P}\}^h = \phi_{3f}^h (e_{Q,P})$$
(7)

$$\left\{a_{Q,P}\right\}^{h} = \left\{\frac{exp(\alpha_{ij})}{\sum_{i=0}^{h} exp(\alpha_{ij})} v_{i}\right\}_{i=0}^{h}; \quad \left\{\alpha_{ij}\right\}^{1} = \frac{q_{i}k_{j}}{\sqrt{2h}}$$
(8)

$$\left\{o_{Q,P}\right\}^{|y|} = Softmax\left(\phi_h^{|y|}(a_{Q,P})\right) \tag{9}$$

where h is the number of hidden units in the attention layers and, $q_{Q,P}, k_{Q,P}$ and $v_{Q,P}$ are the query, key and value vectors, respectively, obtained using independent linear transformation layers

 $\phi_{3f}^h:\mathbb{R}^{3f}\to\mathbb{R}^h$ for the attention layer. α_{ij} is the attention weight assigned to the interaction between i^{th} query and j^{th} key feature. $\phi_h^{|y|}:\mathbb{R}^h\to\mathbb{R}^{|y|}$ is a dense layer for feature compression to the final number of classes and $Softmax(\cdot)$ is used to map the final set of features to the probability space for loss computation as:

$$L(o_{Q,P}, y_k) = -\sum_{k=1}^{|y|} y_k \log(o_{Q,P}); y_k = \begin{cases} 1, & \text{if class is k} \\ 0, & \text{otherwise} \end{cases}$$
 (10)

Handling Multi-Regionality. SALAM uses a two-phase approach of pre-training on the all the regions together and further fine-tuning on particular regions to utilize the entire volume of training data and add regional specificity, respectively. This approach shows significant improvement in performance (as shown in Section 4.3) compared to the single phase training framework.

3.3 Implementation Details

SALAM is implemented using Pytorch framework [23] on a single Nvidia V100 GPU with 4GB VRAM. The model is optimized using AdamW [16] with standard beta parameters of 0.9 and 0.999 and a weight decay rate of 0.01. The language model adopted for text

encoding is XLM-Roberta-base with the standard parameter setting given in [5]. We limit our node neighborhood to a depth of n = 2with a maximum neighborhood size of N = 100. For the graph encoding, we utilize a 2-layer GCN model (L = 2) with 16 hidden units. The raw feature set of the nodes and text encoding of the language model is of F = 768 dimensions which is scaled down to f = 16 (empirically determined) for computational efficiency. The pooling is done on a single head attention network with h = 8hidden units in the linear transformations. The loss function used for gradient descent is binary cross entropy weighted by the class distribution of the samples in the training dataset. SALAM is trained and evaluated on three classification variants of the ESCI search relevance with following unique downstream applications: (i) E vs S vs C vs I, (ii) E vs S vs CI, and (iii) E vs SCI. The code and evaluation of our method is already made publicly available at https://github. com/amazon-research/structure-aware-language-models/.

3.4 Training and Inference Pipeline

In an industrial setting, the training and inference phases have their unique set of requirements both in terms of model latency and complexity. In this section, we explain our pipelines that were designed to meet the general industry requirements.

During the **training phase**, depicted in Figure 3b, the model can have access to a significant amount of both memory (RAM/disk) and compute power (GPUs). More importantly, we also observe that a significant portion (70%-80%) of queries received by e-commerce search engines remain constant over the days of a month, and thus, we consider a monthly update cycle for our model checkpoints. Hence, the training phase also gets a significant amount of time due to the monthly entropy of the underlying dataset (i.e., update frequency). Thus, SALAM's dependence on graph pre-computation (a time intensive operation) and query-product pairing (a memory intensive operation) can be managed in practice. However, one limitation remains that the model checkpoints need to be industrycompliant, and hence, the number of model parameters are resourcedependent (generally a single GPU). For this, we choose our hyperparameters (as given in Section 3.3) to limit model size to 2.5 GB (remaining GPU memory post overhead allocation). The training pipeline receives the query-product pair from the query database and product catalogue, with a manually assigned ESCI label. This information is used to pre-compute the node neighborhoods from purchase information and to train the SALAM architecture, whose parameters are further stored as a checkpoint upon convergence. The checkpoint is further finetuned to region-specific checkpoints using the same procedure, but with only region-specific datasets.

For the **inference phase**, presented in Figure 3c, the model's requirement is to handle a large number of query-product pairs. Due to this, the model's scalability and latency become the primary concerns. Hence, we only use the pre-computed node neighborhood (no computation during inference) and limit our compute power to a single GPU. The inference pipeline initiates an instance of the SALAM model and loads the parameters from the latest checkpoint. Subsequently, it processes the query-product pairs and their node neighborhoods (computed during training) received as input to predict the relevance labels and stores them in a database for utilization in the e-commerce engine's relevance computation pipeline. Note that, the inference pipelines for different regions is

unique and accordingly utilize the corresponding region-specific model checkpoints.

Further experiments on the evaluation of training and inference pipelines are presented in Sections 4.2 and 4.5, respectively. The training and inference algorithms are detailed in Appendix A.

4 EXPERIMENTAL STUDY

In this section, we describe our experimental setup that analyzes SALAM's performance on the ESCI classification tasks compared to its current alternatives. The experiments intend to answer the following research questions:

- **RQ1.** Does SALAM outperform the current alternatives on the task of search relevance classification?
- **RQ2.** Is the two-phase training with pre-training and fine-tuning better than the alternative training frameworks?
- RQ3. What are the considerations in the choice of graph encoders?
- **RQ4.** How does SALAM compare to its alternatives in suitability for an industrial application?

4.1 Datasets and Baselines

The datasets used in our experiments contain $\approx 12M$ manually annotated query-product ESCI pairs collected from the real-world queries of an e-commerce search engine. The pairs are collected from 16 different e-commerce site regions³ with queries in various languages. No customer information or personally identifiable information were used in collecting this data. We evaluate the performance of our model on the following three different downstream tasks of the e-commerce search engine: (i) Four class (E vs S vs C vs I): applied in complementary item recommendation [12], (ii) Three class (E vs S vs CI): applied in alternate product suggestion [3] and (iii) Two class (E vs SCI): for better precision in product recommendation [4]. Each one of these three variants leads to different class distributions which is adjusted in our model using class weights of the binary cross entropy loss. 20% of each region's dataset is held-out for testing and the other 80% is divided into a training and validation ratio of 4:1 for 5-fold cross validation in our experiments. More details on the various e-commerce regions and the class distributions are given in Appendix B.

For the baselines, we consider the publicly available mBERT [8] and XLM [6] models as well as the multilingual proprietary framework, hereinafter, referred to as *proprietary e-commerce baseline (or) PEBL*. The reason for the baseline choice is the multilingual nature of our experiments. The models are all first trained on a combined training dataset of all the regions for a small number of epochs (4 in our case), and then fine-tuned on the region-specific datasets for a larger number of epochs (20 in our case) to finally get the region-specific checkpoints used in our experimental studies.

4.2 **RQ1: Model Performance**

In this experiment, we compare SALAM's performance against the baselines on the task of search relevance classification. The candidate models return a single class for each input query-product pair and the performance is evaluated on the metrics of precision,

³ Australia (AU), Canada (CA), India (IN), Singapore (SG), United Kingdom (UK), United States (US), Japan (JP), Germany (DE), France (FR), Italy (IT), Spain (ES), Netherlands (NL), Turkey (TR), United Arab Emirates (AE), Mexico (MX), and Brazil (BR).

Table 1: Performance comparison of SALAM against the baselines on the task of search relevance classification in different e-commerce regions on four class E-S-C-I classification. The metrics used for evaluation are Precision (P), Recall (R), and F1. The metrics are presented for each class to avoid bias from class distribution and a macro-average over the classes is provided in column M. Due to the proprietary nature of the models, the results shown are relative to the public mBERT model, i.e., a cell value of x implies that the model performs $(1+x) \times$ mBERT. The best results in each segment are highlighted in bold. All the F1-improvements of SALAM over PEBL and mBERT are statistically significant with a p-value threshold of 0.05.

recall, and F-score. The results of our experiments on the four class variant of the problem are given in Table 1. Results on other variants follow a similar trend and are provided in Appendix C.

From our results, we observe that SALAM consistently outperforms both the baselines on F1-score across all regions and classes upto 65% (on an average by 15%). While SALAM is able to provide higher precision than the previous baselines for the 'E' class in several regions such as AU, CA, IN, and others, the major boost

in overall performance is driven by improvement in performance on the classes of S, C, and I. This demonstrates SALAM's ability to leverage the graph information to learn better discriminative features unaffected by the innate class imbalance of the datasets. Also, we note that the performance improvement for the regions with highest number of data samples, i.e., IN, UK, and US is also the highest at 11%, 23%, and 24%, respectively. This implies that SALAM is able to learn better discriminative features with higher number

of training samples. Furthermore, we note that the average performance improvement on majority English language e-commerce regions is 13.5% and non-English language e-commerce regions is 7.9%. However, comparing the regions of English CA and non-English TR with similar number of data samples, we observe that the performance improvement is comparable at $\approx 6\%$. Hence, we conclude that, while the stand-alone performance is high, the reason for lower performance boost in non-English language regions is caused by a lower number of data samples and not due to the model architecture. Another point to note is that the SALAM's performance is 30% - 80% higher than XLM. Given that XLM is the language model used in SALAM, this performance gain demonstrates the main advantage of including graph information in the task of search relevance classification.

4.3 RQ2: Two-phase Learning Framework

To confirm the effectiveness of the two-phase learning framework with region-agnostic pre-training and region-specific fine-tuning, we compare it against a single phase training and validation approach. To get the single phase model (SALAM-S), we train the model on the combined training datasets of all the models but for a larger number of epochs (24 in this experiment)⁴. The comparison metrics are precision, recall, and F1. The results of this experiment are presented in Table 2.

Table 2: Loss in performance by using a single phase training framework (SALAM-S) in comparison to the two phase training model. The metrics are relative to the performance of SALAM, i.e., a cell value of x implies that SALAM-S performs $(1+x) \times SALAM$.

Region	P	R	F1	Region	P	R	F1
AU	154	110	150	FR	054	265	207
CA	080	197	153	IT	129	153	148
IN	107	089	117	ES	085	117	106
SG	097	062	080	NL	070	134	107
UK	030	175	124	TR	040	097	071
US	055	155	121	AE	038	072	061
JP	159	182	174	MX	069	114	102
DE	103	212	171	BR	076	070	073

From our results, we observe that two-phase learning improves the performance on test set by 3%-27% when compared to a single-phase framework trained on the same number of epochs. This exhibits the unique nature of each region's e-commerce queries and promotes the case for region-specific fine-tuning even in the case of multilingual models.

4.4 RQ3: Graph Encoders

For this experiment, we select the popular graph representation frameworks of DeepWalk, Chebyshev, Simple Graph Neural Network (GNN), Graph Recurrent Network (GRN), Graph Convolution Networks (GCN), and Graph Attention Network (GAT) as our candidates. We replace the neighborhood aggregation module with the candidate graph networks in our comparative analysis. To select the graph encoder, we primarily consider the performance metrics

of precision, recall, and F1, but in a computationally restrained (to 4GB of VRAM) setting to simulate industry setup. The results of our study are presented in Table 3.

Table 3: Comparison between variants of SALAM with different graph encoders. The results are shown relative to the performance of the DeepWalk variant, i.e., a cell value of x implies that the variant performs $(1+x) \times \text{DeepWalk}$.

Model Variant	P	R	F1
SALAM- DeepWalk [25]	.000	.000	.000
SALAM-GNN [34]	.126	.498	.327
SALAM-GRN [39]	.167	.557	.377
SALAM-GAT [31]	.208	.616	.427
SALAM-Chebyshev [7]	.213	.627	.435
SALAM-GCN [15]	.235	.678	.472

In our analysis, we observe that given the industry-level memory constraints, the GCN network performs the best in the classification task and hence, we select it as the graph encoder in SALAM.

4.5 RQ4: Practical Environment

In this section, we analyze the memory requirements and processing speed of the model's training and inference pipeline and compare it against the baselines for its suitability to an industrial application⁵.

Table 4: Memory and processing requirements of different models in the training and inference pipeline. The columns present the number of parameters (Param), pre-training time (PTT), fine-tuning time (FTT), inference time (IT), VRAM requirement (Mem), and disk space requirement (Disk). PTT and FTT are provided in seconds per epoch and IT is given in milliseconds per sample. Mem and Disk requirements are given in Gigabytes.

Model	Param	PTT	FTT	IT	Mem	Disk
mBERT	110M	128K	215	10.67	1.01	16.2
XLM	270M	133K	229	10.87	2.49	39.8
PEBL	150M	130K	217	10.83	1.38	22.1
SALAM	279M	135K	231	11.05	2.57	169.1

From Table 4, we note that our model and the baselines have similar memory requirements to the XLM model and conforms to the constraints of a general industrial application environment. Additionally, we note that the increase in training and inference times of SALAM when compared to PEBL is within $\approx 3\%$ and $\approx 2\%$, respectively. Given the monthly build timelines, the difference is negligible even for a larger scale of data. However, a significant challenge is the graph pre-computation module. Given, the large scale of product catalogues and the frequency of queries, it is computationally challenging to retrieve the local neighborhood during inference. Hence, we utilize the training set and purchase information to pre-compute the local neighborhoods and store it as a hash-table for O(1) retrieval during inference. The inductive nature of SALAM ensures language model-level results are available for the non-covered infrequent queries. However, when compared to PEBL, the graph adds to a huge disk requirement (128GB) and additional maintenance in practice.

⁴Note that the two phase approach uses 4 epochs for pre-training and 20 for finetuning, so to maintain a fair comparison we train the single phase with 24 epochs.

 $^{^{5}\}mathrm{generally}$ 4GB of VRAM, 16 GB RAM, and 1TB of disk space.

Figure 4: SALAM Workflow. The existing annotation module can seamlessly be integrated with the training and inference module of our model. The additional disk requirement for the pre-computed graph database is trivial and within limits of general industrial settings.

5 DISCUSSION

In this section, we describe the strategy to deploy SALAM in an industrial application and discuss its impact to e-commerce search.

5.1 Deployment Strategy

As illustrated in Figure 4, SALAM can be trained offline using manually annotated datasets and region-specific checkpoints can be stored for inference. One can load these checkpoints to unique SALAM instances for the different e-commerce regions and deploy the model in a industrial setting using the LuaJIT⁶ platform. LuaJIT loads the model in-memory for real-time inference, removing the additional overhead of weight transfer from disk to GPU memory. In accordance with the inference pipeline, query-product pairs can be processed in batches on multiple processing units and the labels saved for further utilization in downstream modules. For any workflow that already uses query-product pair as an input for classification, integration of SALAM with such workflows is trivial with minor changes. The graph preprocessing operation is also cached and looked up in real-time. Specifically, given the long tailed nature of product search queries, one can precompute query and product neighborhoods for the samples that correspond to the majority of traffic. Efficient online inference methods can also be used to compute the representations in real-time for the tail. Given the performance gains from the graph information and negligible difference in inference time, deploying SALAM makes it a viable investment in practice.

5.2 Contribution to the search engine

In this section, we describe the impact of having an ESCI classifier in a product search engine. E-commerce product search ranking depends on lexical, behavioral, and semantic matching. Behavioral data can sometimes be noisy, and this leads to biases in the data used to train these models (see for e.g., [20]). Having a classifier perform an ESCI-based classification at the final stage, or use these as inputs to other downstream models can help reduce these issues. Results from these models can also be used for customer messaging as to why a certain item was shown in response to a query; for example, why a charger was shown for a phone query. Improving the

performance of ESCI classifiers can thus help improve both product search quality and the trust customers place in these systems, helping practitioners better serve their customers in turn.

6 CONCLUSION

In this paper, we presented Structure-Aware multilingual LAnguage Model (SALAM), a hybrid text and graph based model, that uses a language model in congruence with a GCN network to respectively capture both semantic and relational information for the task of ESCI classification. We have shown the effectiveness of our model in comparison to the currently used alternatives on multiple ESCI classification problem variants. Additionally, we have also demonstrated the effectiveness of a two-phase training setup in handling multiple e-commerce regions, as well as empirically demonstrated our choice of the graph encoder. Moreover, we have also compared SALAM with its alternatives in terms of memory and processing requirements during inference and also detailed its case for deployment in existing industrial pipelines.

A SALAM ALGORITHMS

Algorithms 1 and 2 are the training and inference process flows of the SALAM model, respectively.

Algorithm 1: SALAM training flow.

```
Input: Query-product pairs x = \{(Q, P)\}, Pre-computed
              neighborhoods x_G = \{(Q_G, P_G)\}, Ground truth y;
   Output: Predictor P_{\theta}, \theta;
1 Initialize model parameters \theta;
2 for number of epochs; until convergence do
        Initialize loss l = 0;
3
         for (Q, P) \in x, (Q_G, P_G) \in x_G do
4
              # Process through language model
              t_{Q,P} = \phi_F^f(XLM(Q,P)); \text{ using Eq. (2)}
              # Aggregate node neighborhoods
              g_{O,P} = GCN(Q_G) \circ GCN(P_G); using Eq. (5)
              # Attention Pooling
              e_{O,P} = t_{O,P} \circ g_{O,P}; using Eq. (6)
10
             q_{Q,P} = \phi_{3f}^{h} (e_{Q,P}); \text{ using Eq. (7)}
11
              k_{Q,P} = \phi_{3f}^{\vec{h}} (e_{Q,P}); \text{ using Eq. (7)}
12
              v_{Q,P} = \phi_{3f}^{h}(e_{Q,P}); \text{ using Eq. (7)}
13
             a_{Q,P} = \left\{ \frac{exp(\alpha_{ij})}{\sum_{j=0}^{h} exp(\alpha_{ij})} v_i \right\}_{i=0}^{h}; \text{ using Eq. (8)}
14
             o_{Q,P} = Softmax\left(\phi_h^{|y|}(a_{Q,P})\right); \text{ using Eq. (9)}
15
              # Loss Calculation
             l = l + L(o_{Q,P}, y_k); using Eq. (10)
17
18
         \theta \leftarrow \theta - \nabla_{\theta} l; # Update parameters
19
   end
21 return P_{\theta}, \theta
```

Algorithm 2: SALAM inference flow.

```
Input: \{(Q,P)\}, \{(Q_{\mathcal{G}}, P_{\mathcal{G}})\}, \text{ Region-specific Model Parameters } \theta_r;
Output: Label y_k;

1 t_{Q,P} = \phi_{F,\theta_r}^f(XLM_{\theta_r}(Q,P)); \text{ using Eq. (2)}
2 g_{Q,P} = GCN_{\theta_r}(Q_{\mathcal{G}}) \circ GCN_{\theta_r}(P_{\mathcal{G}}); \text{ using Eq. (5)}
3 # Attention Pooling
4 e_{Q,P} = t_{Q,P} \circ g_{Q,P}; \text{ using Eq. (6)}
5 q_{Q,P} = \phi_{3f,\theta_r}^h(e_{Q,P}); \text{ using Eq. (7)}
6 k_{Q,P} = \phi_{3f,\theta_r}^h(e_{Q,P}); \text{ using Eq. (7)}
7 v_{Q,P} = \phi_{3f,\theta_r}^h(e_{Q,P}); \text{ using Eq. (7)}
8 a_{Q,P} = \left\{\frac{exp(\alpha_{ij})}{\sum_{j=0}^h exp(\alpha_{ij})}v_i\right\}_{i=0}^h; \alpha_{ij} = \frac{q_ik_j}{\sqrt{2h}}; \text{ using Eq. (8)}
9 o_{Q,P} = Softmax\left(\phi_{h,\theta_r}^{|y|}(a_{Q,P})\right); \text{ using Eq. (9)}
10 y_k = \arg\max(o_{Q,P})
11 \mathbf{return} y_k
```

B DATASET DETAILS

In this section, we study the different details of our dataset which contains a total of $\approx 12M$ annotated samples with E-S-C-I labels. The dataset is subsampled for annotation and does not, in any way, represent the exact query volumes received by e-commerce engines. On an average, 71.8%, 15.1%, 8.1%, and 4.9% of the overall dataset are E, S, C, and I classes. We notice that the *Exact* class is a significantly dominant part of the dataset and there is an apparent class imbalance. Hence, to handle the imbalance we use cross entropy with class weights computed as given in [14].

Figure 5 depicts the distribution of our dataset across the different e-commerce regions. We observe that the regions of US and IN constitute $\approx 37\%$ of the total number of samples and consequently, also show higher performance improvements in our experiments (given in Section 4). The rest of regions are similarly distributed of the remaining 63% and hence show comparable performance gains.

Figure 5: Regional distribution of our dataset. The areas of the chart present the size of different e-commerce regions in the overall composition of our dataset⁷.

C FURTHER RESULTS

Table 5 presents results on the three class (E vs S vs CI) and two class (E vs SCI) classification variants of the search relevance problem that are applied to various downstream applications in the e-commerce engine. An example application of the three class problem is alternate product suggestion and that of the two class problem is high precision product search.

 $^{^7{}m The}$ sample distribution of the datasets is given in (%) due to its proprietary nature.

Table 5: Performance comparison of SALAM against the baselines on the task of search relevance classification in different e-commerce regions for three class E-S-CI and two class E-SCI classification. The evaluation metrics are Precision (P), Recall (R), and F1. The metrics are presented for each class to avoid bias from class distribution. Due to the proprietary nature of the models, the results shown are relative to the public mBERT model, i.e., a cell value of x implies that the model performs $(1+x) \times mBERT$. The best results in each segment are highlighted in bold. All the F1-improvements of SALAM over PEBL and mBERT are statistically significant with a p-value threshold of 0.05.
